

# 1 Coreset for Optimal Decision Tree

## 1.1 Notation

Let  $\infty$  be a value s.t.  $-\infty < r < \infty$  for every real  $r \in \mathbb{R}$  and let  $d$  and  $H$  be a pair of positive integers.

The document uses numpy-like notation: a vector is a matrix with one column; a matrix is indexed using square brackets; matrix indexes start from 0;  $[]$  is a matrix with 0 rows and 0 columns; for a pair of matrices  $A$  and  $B$ :  $[A; B]$  is their concatenation; for an integer  $i$  and a matrix  $A$ :  $A[:, i]$  is the  $i$ -th column of  $A$  and  $A[i, :]$  is the  $i$ -th row of  $A$  (which are also matrices).

$\text{sort}(A, i)$  is the matrix  $A$  with its rows reordered to make the values of  $i$ -th column grow ascendingly and  $\text{reverse}(A)$  is the matrix  $A$  with its rows reversed (the first row becomes the last); a matrix whose element's values are either True or False is called *boolean*; binary operations on a matrix and a scalar or a set are performed piecewise on the elements of the matrix; for a boolean array  $B$  and a matrix  $A$  with the same number of rows, the matrix  $A[B, :]$  is the matrix  $A$  with rows whose index not in  $\{i \mid B[i] = \text{True}\}$  removed; a set of  $n$  points  $S \subset \mathbb{R}^d$  and an  $n \times d$  real matrix  $M$  are *equivalent* if for every  $p \in P$  there is  $i \in [n - 1] \cup \{0\}$  such that  $j$ -th coordinate of  $p$  equals the value of  $M[i, j - 1]$  for every integer  $j \in [d]$ ; for every matrix  $M$ ,  $\text{set}(M)$  is the equivalent set of  $M$  and for every set  $S$ ,  $\text{matrix}(S)$  is an arbitrarily chosen equivalent matrix of  $S$ .

Let  $\mathcal{A} : [H] \cup \{0\} \rightarrow [d - 1] \cup \{0\}$  be a function which assigns split axis to each tree height.

## 1.2 Definitions

For every positive integer  $n$ , for every  $n \times d$  real matrix  $P$ , for every positive integer  $h$  and for every real  $t$  we define:

$$\begin{aligned} \text{opt}(P, 0) &:= \max_{p, q \in \text{set}(P)} \|p - q\| \\ \mathcal{L}(P, h, t) &:= P[P[:, \mathcal{A}(h)] \leq t, :] \\ \mathcal{R}(P, h, t) &:= P[P[:, \mathcal{A}(h)] > t, :] \\ \text{opt}(P, h) &:= \max_{t \in \mathbb{R}} \sum_{Q \in \{\mathcal{L}(P, h, t), \mathcal{R}(P, h, t)\}} \text{opt}(Q, h - 1) \end{aligned}$$

and

$$\begin{aligned} lcost(P, h, t) &:= \text{opt}(\mathcal{L}(P, h, t), h - 1) \\ rcost(P, h, t) &:= \text{opt}(\mathcal{R}(P, h, t), h - 1) \\ cost(P, h, t) &:= lcost(P, h, t) + rcost(P, h, t) \end{aligned}$$

### 1.3 Algorithm

**Algorithm 1.1:** BASE( $P$ )

```

 $PQ \leftarrow \{(p, q) \in \text{set}(P)^2 \mid \|p - q\| = cost(P)\}$ 
 $P \leftarrow \text{matrix}(\{p \mid (p, q) \in PQ\})[0, :]$ 
 $Q \leftarrow \text{matrix}(\{q \mid (p, q) \in PQ\})[0, :]$ 
return  $([P; Q])$ 

```

**Algorithm 1.2:** OT-CORESET( $P, \mathcal{A}, \varepsilon, h$ )

```

if  $h = 0$ 
  then return  $(\text{BASE})(P)$ 
else
   $C \leftarrow [], Q \leftarrow [], L \leftarrow [], X \leftarrow \{P\}$ 
  for each  $M \in \{\text{sort}(P), \text{reverse}(\text{sort}(P))\}$ 
    do for  $i \leftarrow 0$  to  $|\text{set}(M)| - 1$ 
       $p \leftarrow M[i, :]$ 
      if  $\text{opt}([Q; p], h - 1) \geq (1 + \varepsilon) \cdot \text{opt}(L, h - 1)$ 
        do
          then
             $\text{output } (p[\mathcal{A}(h)])$ 
             $L \leftarrow Q$ 
             $R \leftarrow \text{matrix}(\text{set}(P) \setminus \text{set}([L; p]))$ 
             $X \leftarrow X \cup \{L, R, [L; p], [R; p]\}$ 
           $Q \leftarrow [Q; p]$ 
      for each  $x \in X$ 
        do
           $c \leftarrow \text{OT-CORESET}(x, \mathcal{A}, \varepsilon, h - 1)$ 
           $C \leftarrow [C; c]$ 
  return  $(C)$ 

```

### 1.4 Analysis

**Theorem 1.** *Let  $P$  be an  $n \times d$  real matrix, let  $h \leq H$  be a nonnegative integer and let  $t$  be a real. Then for  $C = \text{OT-CORESET}(P, \mathcal{A}, \varepsilon, h)$ ,  $cost(C, h, t)$  is an  $(1 + \varepsilon)^h$ -approximation of  $cost(P, h, t)$ .*

*Proof.* We claim that if  $A$  is a subset of  $P$  then for every nonnegative integer  $h \leq H$ , for every real  $t$  and for  $C = \text{OT-CORESET}(P, \mathcal{A}, \varepsilon, h)$ :

$$(1 - \varepsilon)^h \text{cost}(P, h, t) \leq \text{cost}(C \cup A, h, t) \leq (1 + \varepsilon)^h \text{cost}(P, h, t)$$

and we prove our claim by induction on  $h$ .

For  $h = 0$ , let  $m$  be the number of rows printed by the algorithm and let  $t_1, \dots, t_m \in \mathbb{R}$  be the output of the algorithm sorted ascendingly; let  $t_0 = -\infty$  and  $t_{m+1} = \infty$  and let  $T = \{t_0, t_1, \dots, t_{m+1}\}$ .

Let  $C_\ell = \text{set}(\text{BASE}(\mathcal{L}(P, 0, t)))$  and let  $C_r = \text{set}(\text{BASE}(\mathcal{R}(P, 0, t)))$ .

If  $t \in T$  then by algorithm construction  $C_\ell, C_r \subseteq C$  and therefore

$$\begin{aligned} \text{lcost}(C, 0, t) &= \text{lcost}(P, 0, t) \\ \text{rcost}(C, 0, t) &= \text{rcost}(P, 0, t) \end{aligned}$$

and therefore  $\text{lcost}(C \cup A, 0, t) = \text{lcost}(P, 0, t)$  and  $\text{rcost}(C \cup A, 0, t) = \text{rcost}(P, 0, t)$  since  $C \subseteq C \cup A \subseteq P$  and since  $\text{lcost}, \text{rcost}$  are monotonic. Therefore

$$\begin{aligned} \text{cost}(C \cup A, 0, t) &= \text{lcost}(C \cup A, 0, t) + \text{rcost}(C \cup A, 0, t) \\ &= \text{lcost}(P, 0, t) + \text{rcost}(P, 0, t) = \text{cost}(P, 0, t). \end{aligned}$$

Otherwise,  $t \notin T$ . Let  $i \in [m+1] \cup \{0\}$  be the largest index such that  $t_i \leq t$  and let  $t_\ell = t_i$  and  $t_r = t_{i+1}$ .

By algorithm construction we have

$$\text{lcost}(P, 0, t_\ell) \leq \text{lcost}(P, 0, t) \leq \text{lcost}(P, 0, t_r) \leq (1 + \varepsilon) \text{lcost}(P, 0, t_\ell)$$

and

$$\text{rcost}(P, 0, t_r) \leq \text{rcost}(P, 0, t) \leq \text{rcost}(P, 0, t_\ell) \leq (1 + \varepsilon) \text{rcost}(P, 0, t_r).$$

Therefore, since  $t_\ell, t_r \in T$

$$\begin{aligned} \text{lcost}(C \cup A, 0, t) &\leq \text{lcost}(C \cup A, 0, t_r) = \text{lcost}(P, 0, t_r) \\ &\leq (1 + \varepsilon) \text{cost}(P, 0, t_\ell) \leq (1 + \varepsilon) \text{cost}(P, 0, t) \end{aligned}$$

and

$$\begin{aligned} \text{rcost}(C \cup A, 0, t) &\leq \text{rcost}(C \cup A, 0, t_\ell) = \text{rcost}(P, 0, t_\ell) \\ &\leq (1 + \varepsilon) \text{rcost}(P, 0, t_r) \leq (1 + \varepsilon) \text{rcost}(P, 0, t) \end{aligned}$$

and therefore

$$\text{cost}(C \cup A, 0, t) \leq (1 + \varepsilon) \text{cost}(P, 0, t).$$

By algorithm construction  $lcost(P, 0, t_r) \leq lcost(P, 0, t_\ell) + \varepsilon lcost(P, 0, t_\ell)$  and therefore

$$lcost(P, 0, t_\ell) \geq lcost(P, 0, t_r) - \varepsilon lcost(P, 0, t_\ell) \geq (1 - \varepsilon)lcost(P, 0, t_r)$$

and similary  $rcost(P, 0, t_r) \geq (1 - \varepsilon)rcost(P, 0, t_\ell)$ . Therefore

$$\begin{aligned} lcost(C \cup A, 0, t) &\geq lcost(C \cup A, 0, t_\ell) = lcost(P, 0, t_\ell) \\ &\geq (1 - \varepsilon)lcost(P, 0, t_r) \geq (1 - \varepsilon)lcost(P, 0, t). \end{aligned}$$

and

$$\begin{aligned} rcost(C \cup A, 0, t) &\geq rcost(C \cup A, 0, t_r) = rcost(P, 0, t_r) \\ &\geq (1 - \varepsilon)rcost(P, 0, t_\ell) \geq (1 - \varepsilon)rcost(P, 0, t) \end{aligned}$$

and therefore

$$cost(C \cup A, 0, t) \geq (1 - \varepsilon)cost(P, 0, t).$$

We now assume that the claim is correct for  $0 \leq h < H$ , that is that for  $C = \text{OT-CORESET}(P, \mathcal{A}, \varepsilon, h)$  and for every  $A \subseteq P$  the following holds

$$(1 - \varepsilon)^h cost(P, h, t) \leq cost(C \cup A, h, t) \leq (1 + \varepsilon)^h cost(P, h, t)$$

and prove that it is also holds for  $h+1$ , when  $C = \text{OT-CORESET}(P, \mathcal{A}, \varepsilon, h+1)$ .

Note, that since the claim holds for every  $t$  we can also say that

$$(1 - \varepsilon)^h opt(P, h) \leq opt(C \cup A, h) \leq (1 + \varepsilon)^h opt(P, h).$$

Let  $m$  be the number of rows printed by the algorithm and let  $t_1, \dots, t_m \in \mathbb{R}$  be the printed output of the algorithm; let  $t_0 = -\infty$  and  $t_{m+1} = \infty$  and let  $T = \{t_0, t_1, \dots, t_{m+1}\}$ .

Let

$$\begin{aligned} C_\ell &= \text{set}(\text{OT-CORESET}(\mathcal{L}(P, 0, t), t), \mathcal{A}, \varepsilon, h) \\ C_R &= \text{set}(\text{OT-CORESET}(\mathcal{R}(P, 0, t), t), \mathcal{A}, \varepsilon, h). \end{aligned}$$

If  $t \in T$  then by algorithm construction  $C_\ell, C_R \subseteq C$ . Let  $A_\ell = C \setminus C_\ell$  and let  $A_R = C \setminus C_R$ .

By definition,  $lcost(P, h+1, t) = opt(\mathcal{L}(P, 0, t), h)$  and  $opt(\mathcal{L}(P, 0, t), h+1) = opt(\mathcal{L}(C_\ell \cup A_\ell, 0, t), h+1)$ . Therefore, by induction assumption

$$\begin{aligned} opt(\mathcal{L}(P, 0, t), h)(1 - \varepsilon)^h &\leq opt(\mathcal{L}(C_\ell \cup A_\ell, 0, t), h) \\ &\leq (1 + \varepsilon)^h opt(\mathcal{L}(P, 0, t), h) \end{aligned}$$

and similarly,

$$\begin{aligned} \text{opt}(\mathcal{R}(P, 0, t), h-1)(1-\varepsilon)^h &\leq \text{opt}(\mathcal{R}(C_r \cup A_r, 0, t), h) \\ &\leq (1+\varepsilon)^h \text{opt}(\mathcal{R}(P, 0, t), h) \end{aligned}$$

and therefore

$$\begin{aligned} \text{cost}(P, h+1, t)(1-\varepsilon)^h &\leq \text{cost}(P, h+1, t) \\ &\leq (1+\varepsilon)^h \text{cost}(P, h+1, t). \end{aligned}$$

If  $t \notin T$  let  $i \in [m+1] \cup \{0\}$  be the largest index such that  $t_i \leq t$  and let  $t_\ell = t_i$  and  $t_r = t_{i+1}$ .

By algorithm construction we have

$$\text{lcost}(P, 0, t_\ell) \leq \text{lcost}(P, 0, t) \leq \text{lcost}(P, 0, t_r) \leq (1+\varepsilon)\text{lcost}(P, 0, t_\ell)$$

and

$$\text{rcost}(P, 0, t_r) \leq \text{rcost}(P, 0, t) \leq \text{rcost}(P, 0, t_\ell) \leq (1+\varepsilon)\text{rcost}(P, 0, t_r).$$

Therefore, since  $t_\ell, t_r \in T$

$$\begin{aligned} \text{lcost}(C \cup A, 0, t) &\leq \text{lcost}(C \cup A, 0, t_r) \leq (1+\varepsilon)^h \text{lcost}(P, 0, t_r) \\ &\leq (1+\varepsilon)^h (1+\varepsilon) \text{cost}(P, 0, t_\ell) \leq (1+\varepsilon)^{h+1} \text{cost}(P, 0, t) \end{aligned}$$

and

$$\begin{aligned} \text{rcost}(C \cup A, 0, t) &\leq \text{rcost}(C \cup A, 0, t_\ell) \leq (1+\varepsilon)^h \text{rcost}(P, 0, t_\ell) \\ &\leq (1+\varepsilon)^h (1+\varepsilon) \text{rcost}(P, 0, t_r) \leq (1+\varepsilon)^{h+1} \text{rcost}(P, 0, t) \end{aligned}$$

and therefore

$$\text{cost}(C \cup A, 0, t) \leq (1+\varepsilon)^{h+1} \text{cost}(P, 0, t).$$

By algorithm construction  $\text{lcost}(P, 0, t_r) \leq \text{lcost}(P, 0, t_\ell) + \varepsilon \text{lcost}(P, 0, t_\ell)$  and therefore

$$\text{lcost}(P, 0, t_\ell) \geq \text{lcost}(P, 0, t_r) - \varepsilon \text{lcost}(P, 0, t_\ell) \geq (1-\varepsilon) \text{lcost}(P, 0, t_r)$$

and similarly  $\text{rcost}(P, 0, t_r) \geq (1-\varepsilon) \text{rcost}(P, 0, t_\ell)$ . Therefore

$$\begin{aligned} \text{lcost}(C \cup A, 0, t) &\geq \text{lcost}(C \cup A, 0, t_\ell) \geq (1-\varepsilon)^h \text{lcost}(P, 0, t_\ell) \\ &\geq (1-\varepsilon)^h (1-\varepsilon) \text{lcost}(P, 0, t_r) \geq (1-\varepsilon)^{h+1} \text{lcost}(P, 0, t). \end{aligned}$$

and

$$\begin{aligned} rcost(C \cup A, 0, t) &\geq rcost(C \cup A, 0, t_r) \geq (1 - \varepsilon)^h rcost(P, 0, t_r) \\ &\geq (1 - \varepsilon)^h (1 - \varepsilon) rcost(P, 0, t_\ell) \geq (1 - \varepsilon)^{h+1} rcost(P, 0, t) \end{aligned}$$

and therefore

$$cost(C \cup A, 0, t) \geq (1 - \varepsilon) cost(P, 0, t).$$

□

## 2 Approximate Decision Tree

In this section the value of an empty sum is 0. Let  $\varepsilon \in (0, 1) \subset \mathbb{R}$  be a real number in the open interval  $(0, 1)$ . Let  $d, n \in \mathbb{Z}_{>0}$  be a pair of positive integers. For every  $i \in [d]$  let  $g_i \subset \mathbb{R}$  be a finite set of a coordinates and let  $G = g_1 \times g_2 \times \cdots \times g_d$ .

$G$  imposes a grid, for instance we may choose a  $d$  positive real numbers  $\sigma_1, \dots, \sigma_d \in \mathbb{R}_{>0}$  and  $d$  positive integers  $m_1, \dots, m_d \in \mathbb{Z}_{>0}$  and define

$$g_i := \{\sigma_i, (1 + \varepsilon)\sigma_i, (1 + \varepsilon)^2\sigma_i, \dots, (1 + \varepsilon)^{m_i}\sigma_i\}$$

to make the grid exponentially increasing.

For  $i \in [d]$  and  $p \in \mathbb{R}^d$  we denote the  $i$ -th coordinate of  $p$  by  $p[i]$ . We may treat a point  $p \in \mathbb{R}^d$  as a  $d$ -tuple by writing  $p = (p[1], p[2], \dots, p[d])$ . For a pair of points  $p, q \in \mathbb{R}^d$  we define

$$\gamma(q_1, q_2) := \left\{ p \in \mathbb{R}^d \mid \forall i \in [d] : q_1[i] < p[i] \leq q_2[i] \right\}.$$

Let

$$\begin{aligned} \mu(P, i) &:= \frac{1}{|P|} \cdot \sum_{p \in P} p[i] \\ \lambda(P, i) &:= \min \{p[i] \mid p \in P\} \\ \rho(P, i) &:= \max \{p[i] \mid p \in P\} \end{aligned}$$

For  $i \in [d]$  let

$$A = \gamma(\lambda(G, 1), \dots, \lambda(G, d)), (\rho(G, 1), \dots, \rho(G, d)).$$

For a compact of points  $P \subset A$  and an integer  $i \in [d]$  we define

$$\begin{aligned}\alpha(P) &:= (\mu(P, 1), \mu(P, 2), \dots, \mu(P, d)) \\ \beta(P) &:= \sum_{p \in P} \|p - \alpha(P)\|^2\end{aligned}$$

For a point  $p \in A$  we define

$$\begin{aligned}\Gamma &= \{(q_1, q_2) \in G^2 \mid \forall i \in [d] : q_1[i] < q_2[i]\} \\ \Phi &:= \{\gamma(q_1, q_2) \mid q_1, q_2 \in \Gamma\} \\ \phi(p) &:= \{C \in \Phi \mid p \in C\}\end{aligned}$$

For a set of points  $P \subseteq A$  an integer  $i \in [d]$  and a real  $t \in \mathbb{R}$  we define

$$\begin{aligned}\mathcal{L}(P, i, t) &:= \{p \in P \mid p[i] < t\} \\ \mathcal{R}(P, i, t) &:= P \setminus \mathcal{L}(P, i, t)\end{aligned}$$

For a positive integer  $h$ ,  $h$ -tree is a tuple  $(t, i, L, R)$  where  $i \in [d]$  is an integer,  $t \in g_i$  is a coordinate and  $L, R$  are  $\ell$ -tree and  $r$ -tree respectively for integers  $0 \leq \ell, r < h$  such that either  $\ell = h - 1$  or  $r = h - 1$ ; 0-tree is an empty tuple. For  $h$ -tree  $(t, i, L, R)$  and a finite non-empty set of points  $P \subset A$  we define

$$\begin{aligned}\text{cost}(P, ()) &:= \beta(P) \\ \text{cost}(P, (t, i, L, R)) &:= \text{cost}(\mathcal{L}(P, i, t), L) + \text{cost}(\mathcal{R}(P, i, t), R).\end{aligned}$$

Finally, we define the function  $s : 2^A \times A \rightarrow \mathbb{R}$  to be

$$s(P, p) := \sum_{C \in \phi(p)} \frac{\|\alpha(C \cap P) - p\|^2}{\text{cost}(C \cap P, ())}.$$

We will use the following algorithm in the next theorem.

**Algorithm 2.1:** LEAF( $p, T$ )**comment:**  $p \in A$  and  $T$  is an  $h$ -tree $\ell \leftarrow (\lambda(G, 1), \dots, \lambda(G, d))$  $r \leftarrow (\rho(G, 1), \dots, \rho(G, d))$ **while**  $T \neq ()$ 

<b>do</b>	{	$(t, i, L, R) \leftarrow T$
		<b>if</b> $p[i] \leq t$
		<b>then</b> {
		$r[i] \leftarrow t$
		$T \leftarrow L$
		<b>else</b> {
		$\ell[i] \leftarrow t$
		$T \leftarrow R$
		}
		}

**return**  $(\gamma(\ell, r))$ 

**Theorem 2.** For every positive integer  $h$ , for every set of points  $P \subseteq A$ , for every  $h$ -tree  $T$  and for every  $p \in P$ :

$$\frac{\|\alpha(\text{LEAF}(p, T) \cap P) - p\|^2}{\text{cost}(P, T)} \leq s(P, p)$$

*Proof.* Let  $r, \ell$  be the variables from Algorithm LEAF. These variables are points such that  $r, \ell \in G$ : they are initialized to be points in  $G$  and their coordinates are altered only to values from  $G$ .

Hence:

$$\text{LEAF}(p, T) = \gamma(\ell, r) \in \Phi$$

On the other hand  $p \in \text{LEAF}(p, T)$  since from the construction of Algorithm LEAF follows that for every  $i \in [d] : \ell[i] \leq p[i] \leq r[i]$ .

Let  $C = \text{LEAF}(p, T)$ . Since  $C \in \Phi$  and  $p \in C$ :  $C \in \phi(p)$ .

Therefore, from the definition of  $s(P, p)$  follows that

$$\frac{\|\alpha(C \cap P) - p\|^2}{\text{cost}(C \cap P, ())} \leq s(P, p)$$

On the other hand, from the definition of  $\text{cost}$  follows that

$$\text{cost}(C \cap P, ()) \leq \text{cost}(P, T)$$

and therefore

$$\frac{\|\alpha(C \cap P) - p\|^2}{\text{cost}(P, T)} \leq \frac{\|\alpha(C \cap P) - p\|^2}{\text{cost}(C \cap P, ())}.$$

Hence

$$\frac{\|\alpha(C \cap P) - p\|^2}{\text{cost}(P, T)} \leq s(P, p).$$

□

**Theorem 3.** *For any finite set of points  $P \subset A$ :*

$$\sum_{p \in P} s(P, p) = O(m^{2d})$$

*Proof.*  $G$  is a Cartesian product of  $d$  sets of cardinality  $m$  and therefore  $|G| = m^d$ . Therefore

$$|\Phi| \leq |G^2| = \binom{m^d}{2} = O(m^{2d})$$

and therefore

$$\begin{aligned} \sum_{p \in P} s(P, p) &= \sum_{p \in P} \sum_{C \in \phi(p)} \frac{\|\alpha(C \cap P) - p\|^2}{\text{cost}(C \cap P, ())} = \sum_{C \in \Phi} \sum_{p \in P \cap C} \frac{\|\alpha(C \cap P) - p\|^2}{\text{cost}(C \cap P, ())} \\ &= \sum_{C \in \Phi} \frac{\text{cost}(C \cap P, ())}{\text{cost}(C \cap P, ())} \sum_{C \in \Phi} 1 = |\Phi| = O(m^{2d}). \end{aligned}$$

□

**Theorem 4** (Link to sensitivity article). *Let  $h$  be a positive integer. Let  $\mathcal{T}$  be a set of all  $h$ -trees. For every set of points  $P \subseteq A$ , for every  $h$ -tree  $T$  and for every  $p \in P$*

$$\sum_{p \in P} s(P, p) = O(m^{2d})$$

and

$$\frac{\|\alpha(\text{LEAF}(p, T) \cap P) - p\|^2}{\text{cost}(P, T)} \leq s(P, p)$$

*and therefore for every positive integer  $h$ , for every set of points  $P \subseteq A$ , for every  $h$ -tree  $T$  there is a set of weighted points  $C$  such that and a function  $\text{cost}' : 2^{\mathbb{R} \times \mathbb{R}^d} \times \mathcal{T} \rightarrow \text{real}$  such that*

$$(1 - \varepsilon)\text{cost}(P, T) \leq \text{cost}'(C, T) \leq (1 + \varepsilon)\text{cost}(P, T).$$

### 3 (No) Coreset For Arbitrary Trees

For positive integer  $h$ ,  $h$ -tree is a tuple  $(t, i, L, R)$  when  $t$  is a real,  $i \in [d]$  is an integer and  $L, R$  are  $\ell$ -tree and  $r$ -tree respectively for integers  $0 \leq \ell, r < h$

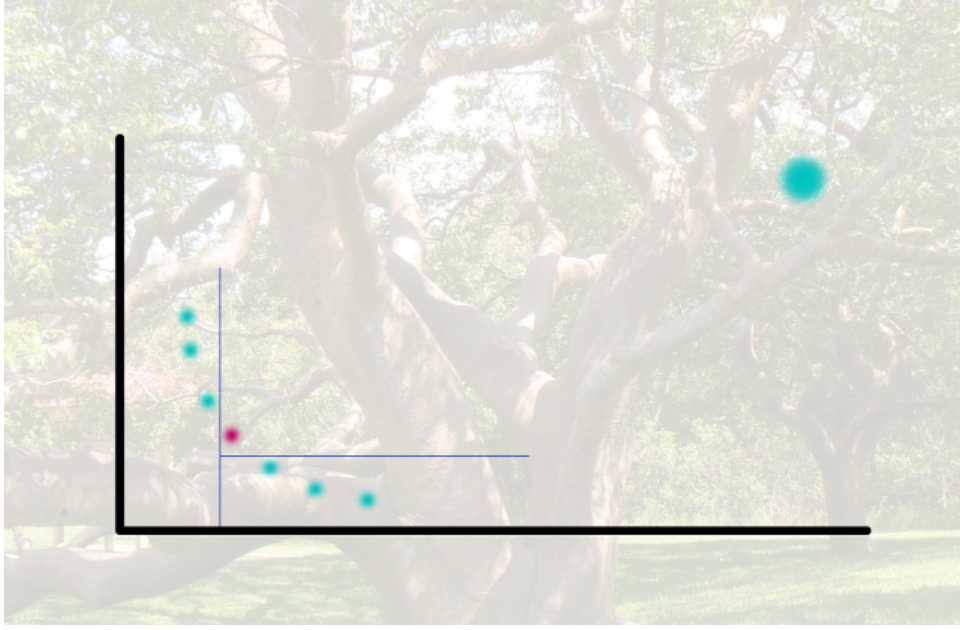

Figure 1: green and red points are in  $P$ , green points are also in  $C$ , blue lines are tree partitions

such that either  $\ell = h - 1$  or  $r = h - 1$ ; 0-tree is an empty tuple. For  $h$ -tree  $(t, i, L, R)$  and a set of points  $P$ :

$$\begin{aligned} \text{cost}(P, ()) &= \text{MSE}(P) \\ \text{cost}(P, (t, i, L, R)) &= \text{cost}(\mathcal{L}(P, i, t), L) + \text{cost}(\mathcal{R}(P, i, t), R) \end{aligned}$$

**Theorem 5.** *Let  $h$  be a positive integer larger than 2. There is a set of points  $P$  such that for every subset  $C \subset P$  there is  $h$ -tree  $T$  such that*

$$\text{cost}(C, T) \not\geq (1 - \varepsilon)\text{cost}(P, T)$$

*Proof.* Let  $n > 10$  be a positive integer. Let  $Q$  be a set of  $n$  random points on a left bottom quarter of a circle centered at  $(1, 1)$  with radius 1. Let  $P = Q \cup \{(n \cdot 2^{11}, n \cdot 2^{11})\}$ . Let  $C \subset Q$ . There is  $p \in P$  such that  $p \notin C$ . If  $p = (n \cdot 2^{11}, n \cdot 2^{11})$  then for  $T = (\infty, 0, (\infty, 0, (\infty, 0, (), ()), ()), ())$ :  $\text{cost}(C, T) \leq n$  and  $\text{cost}(P, T) > n \cdot 2^{10}$  and hence

$$\text{cost}(C, T) \not\geq (1 - \varepsilon)\text{cost}(P, T).$$

Therefore,  $p \neq (n \cdot 2^{11}, n \cdot 2^{11})$ . Hence,  $p$  is one of the points on the quarter circle. Every such point can be separated by an  $h$ -tree, see Figure 1.  $\square$

## 4 Coreset For H=1

### 4.1 Notation

In this section, we use the convention that the value of an empty sum of numbers is 0. For a concatenation of any two row vectors  $\phi = (\phi_1, \dots, \phi_m)$  and  $\chi = (\chi_1, \dots, \chi_m)$  we denote  $(\phi, \chi) = (\phi_1, \dots, \phi_m, \chi_1, \dots, \chi_m)$ . For example, for a real number  $t$  and a vector  $p \in \mathbb{R}^d$ , the pair  $(t, p)$  is a point in  $\mathbb{R}^{d+1}$ .

Here an thereafter, we assume that  $d$  and  $k$  are a pair of positive integers and that  $j \leq d$  is a non-negative integer.

Let  $S$  be an affine subspace of  $\mathbb{R}^d$ . For a real number  $t \in \mathbb{R}$  we define  $S(t)$  to be

$$S(t) := \begin{cases} \{(t, q) \in S\} & |S| > 1 \\ S & \text{otherwise} \end{cases}$$

and we define the (*regression*) *distance* of a point  $(t, p) \in \mathbb{R}^d$  to  $S$  to be

$$D((t, p), S) := \begin{cases} \min_{q \in S(t)} \|(t, p) - q\| & S(t) \neq \emptyset \\ \infty & \text{otherwise.} \end{cases}$$

The point  $q \in S$  is a *projection* of the point  $p \in \mathbb{R}^d$  on  $S$  if  $D(p, S) = D(p, \{q\})$ . Since  $S$  is affine, the distance is well defined and the projection of  $p$  on  $S$  exists and is unique. The *projection of a set*  $P \subseteq \mathbb{R}^d$  on  $S$  is the union of projections of all points in  $P$  on  $S$ .

For a sequence of  $k$  intervals  $I = (I_1, \dots, I_k)$  and a sequence  $\mathbb{R}^d$   $S = (S_1, \dots, S_k)$  of  $k$   $j$ -affine subspaces in  $\mathbb{R}^d$  the *cost* of  $(I, S)$  with respect to a set of points  $P \subseteq \mathbb{R}^d$  is

$$\text{cost}(P, I, S) := \sum_{i=1}^k \max \{D((t, p), S_i) \mid (t, p) \in P, t \in I_i\}.$$

For a sequence  $W = (w_1, \dots, w_k)$  of  $k$  non-negative reals the *cost* of  $(I, S, W)$  with respect to a set of points  $P \subseteq \mathbb{R}^d$  is

$$\mathbf{cost}(P, I, S, W) := \sum_{i=1}^k w_i \text{cost}(P, I_i, S_i).$$

A *j-flat-mean* of  $P \subset \mathbb{R}^d$  is a  $j$ -affine subspace  $S^*$  of  $\mathbb{R}^d$  which minimizes  $\text{cost}(P, \mathbb{R}, S)$  over every  $j$ -affine subspace  $S$  of  $\mathbb{R}^d$ . We denote the *cost* of  $S^*$  over  $\mathbb{R}$  with respect to  $P$  by

$$\text{opt}(P, j) := \text{cost}(P, \mathbb{R}, S^*).$$

## 4.2 Coreset Algorithm

We describe an algorithm which gets a set  $P$  of points in a  $j$ -affine subspace of  $\mathbb{R}^d$  and returns a set of sets of points  $C$  which complies with Claim 6. The algorithm gets as input an error parameter  $\varepsilon > 0$  and a finite set of points  $P \subset \mathbb{R}^d$ .

### 4.2.1 Algorithm Overview

We assume that there is a function  $\text{BASIC-CORESET} : 2^{\mathbb{R}^d} \times \mathbb{R}$  which receives a set of points  $P'$  and an error parameter  $\varepsilon' > 0$  and returns new set of points  $C'$  such that for every query  $Q$

$$\begin{aligned} (1 - \varepsilon) \text{cost}(P', \mathbb{R}, Q) &\leq \text{cost}(C', \mathbb{R}, Q) \\ &\leq (1 + \varepsilon) \text{cost}(P', \mathbb{R}, Q') \end{aligned}$$

Our algorithm is divided into 2 steps, in the first step the points are partitioned into  $m$  buckets  $B_1, \dots, B_m$  where  $m$  is a positive integer and in the second step we perform the following for each  $i \in [m]$ :

1. Let  $p \in B_i$  be a point with the smallest first coordinate in  $B_i$  (ties are broken arbitrarily). Add  $p$  to the coreset.
2. Run  $\text{BASIC-CORESET}(B_1 \cup \dots \cup B_{i-1}, \varepsilon)$  and add the output to the coreset.

Now we proceed to describing step-1 and step-2. When describing the steps, we use the following notation: we say that *adding a point* from a set  $A \subseteq \mathbb{R}^d$  to a set  $B \subseteq \mathbb{R}^d$  is equivalent to performing the following:

1. Picking a point  $(t, q) \in A$  s.t.  $(x, y) \in A : t \leq x$  for every point (ties broken arbitrarily).
2. Setting  $A \leftarrow A \setminus \{(t, q)\}$
3. Setting  $B \leftarrow B \cup \{(t, q)\}$

**Step-1** Initialize  $B_1$  to be an empty set. Then add points from  $P$  to  $B_1$  until either  $P$  is empty or  $\text{opt}(B_1) > 0$ . If  $P$  is empty finish. Set  $m \leftarrow 2$  and repeat until  $P$  is empty:

1. Add points from  $P$  to  $B_m$  while  $\text{opt}(B_m) < \varepsilon \text{opt}(B_1 \cup B_2 \cup \dots \cup B_{m-1})$ .
2. Increase  $m$  by one.

**Step-2** Initialize the coreset  $C$  to be an empty set. For  $i \in [m]$  perform the following:

1. Let  $p = (t, q) \in B_i$  be a point s.t.  $t \leq t'$  for every point  $p' = (t', q') \in B_i$  (ties are broken arbitrarily). Set  $C \leftarrow C \cup \{p\}$ .
2. Run BASIC-CORESET on  $B_1 \cup \dots B_{i-1}$  and  $\varepsilon$  and add the output to the coreset:  $C \leftarrow C \cup \text{BASIC-CORESET}(B_1 \cup \dots \cup B_{i-1}, \varepsilon)$ .

#### 4.2.2 Pseudo-Code

**Algorithm 4.1:** CREATE-CORESET( $\varepsilon, P$ )

**comment:**  $\varepsilon \in \mathbb{R}_{>0}$  is a real and  $P \subset \mathbb{R}^d$  is a finite set of points

**procedure** STEP-1( $P, \varepsilon$ )

$B_1 \leftarrow \emptyset$

**while**  $\text{opt}(B_0) > 0$  **and**  $P \neq \emptyset$

**do**  $\begin{cases} p \leftarrow \text{arbitrary point in } \{(t, p) \in P \mid \forall (t', p') \in P : t \leq t'\} \\ B_1 \leftarrow B_1 \cup \{p\} \\ P \leftarrow P \setminus \{p\} \end{cases}$

$m \leftarrow 1$

**while**  $P \neq \emptyset$

**do**  $\begin{cases} p \leftarrow \text{arbitrary point in } \{(t, p) \in P \mid \forall (t', p') \in P : t \leq t'\} \\ B_m \leftarrow B_m \cup \{p\} \\ P \leftarrow P \setminus \{p\} \end{cases}$

**return**  $(B_1, \dots, B_m)$

**procedure** STEP-2( $B_1, \dots, B_m$ )

$C \leftarrow \emptyset$

**for**  $i \leftarrow 1$  **to**  $m$

**do**  $\begin{cases} p \leftarrow \text{arbitrary point in } \{(t, p) \in B_i \mid \forall (t', p') \in B_i : t \leq t'\} \\ C \leftarrow C \cup \{p\} \\ C \leftarrow C \cup \text{BASIC-CORESET}(B_1 \cup \dots \cup B_{i-1}, \varepsilon). \end{cases}$

**return**  $(C)$

**main**

$B_1, \dots, B_m \leftarrow \text{STEP-1}(P, \varepsilon)$

**return**  $(\text{STEP-2}(B_1, \dots, B_m))$

#### 4.3 Algorithm Guarantees

**Theorem 6.** Let  $\varepsilon > 0$  be a real number and let  $P$  be a set of points in  $\mathbb{R}^d$  and let  $C$  be the output of Algorithm ?? running on  $P$  and  $\varepsilon$ . Let  $t \in \mathbb{R}^d$

and let  $I = (-\infty, t]$  be an interval. Then for every point  $q \in \mathbb{R}^d$  we have

$$\begin{aligned} (1 - \varepsilon) \text{cost}(P, I, \{q\}) &\leq \text{cost}(C, I, \{q\}) \\ &\leq (1 + \varepsilon) \text{cost}(P, I, \{q\}) \end{aligned}$$

*Proof.* Let  $\{B_1, \dots, B_m\}$  be the partition of  $P$  into  $m$  buckets as returned by the algorithm. Let  $\{I_1, \dots, I_m\}$  be a partition of  $\mathbb{R}$  by set of intervals such that  $I_i$  contains the first coordinate of every point in  $B_i$  for  $i \in [m]$ . Let  $i \in [m]$  be an integer such that  $t \in I_i$ . Let  $p' \in \mathbb{R}^d$  be a point s.t.  $p' \in B_i$  and  $p' = (x', y')$  and  $x' \leq t$ , such a point exists because of algorithm construction.

If there is a point  $p \in B_1 \cup \dots \cup B_{i-1}$  such that  $\text{cost}(\{p\}, I, \{q\}) = \text{cost}(P, I, \{q\})$  then

$$\begin{aligned} (1 - \varepsilon) \text{cost}(P, I, \{q\}) &\leq \text{cost}(C, I, \{q\}) \\ &\leq (1 + \varepsilon) \text{cost}(P, I, \{q\}) \end{aligned}$$

because  $C$  contains  $\text{BASIC-CORESET}(B_1 \cup \dots \cup B_{i-1}, \varepsilon)$ .

Otherwise, there must be  $p \in B_i$  such that  $\text{cost}(\{p\}, I, \{q\}) = \text{cost}(P, I, \{q\})$ . From lemma 7.1 in [?] follows that for every pair of points  $a, b, c \in \mathbb{R}^d$ , for every  $\sigma \in (0, 1)$ :

$$|D^2(a, c) - D^2(b, c)| \leq \frac{12D^2(a, b)}{\sigma} + \frac{\sigma}{2} D^2(a, c).$$

By choosing  $\sigma = \sqrt{\varepsilon}$  we get:

$$|D^2(q, p) - D^2(q, p')| \leq \frac{12D^2(p, p')}{\sqrt{\varepsilon}} + \frac{\sqrt{\varepsilon}}{2} D^2(q, p').$$

From algorithm construction we have:

$$\frac{12D^2(p, p')}{\sqrt{\varepsilon}} \leq \frac{12 \cdot 4\varepsilon \text{cost}(C, I, \{q\})}{\sqrt{\varepsilon}}$$

and on the other hand

$$D^2(q, p') \leq \text{cost}(C, I, \{q\})$$

since  $p' \in C$ . Therefore

$$\begin{aligned} |D^2(q, p) - D^2(q, p')| &\leq 48\sqrt{\varepsilon} \text{cost}(C, I, \{q\}) \\ &\quad + \frac{\sqrt{\varepsilon}}{2} \text{cost}(C, I, \{q\}) \\ &\leq 48\sqrt{\varepsilon} \text{cost}(C, I, \{q\}). \end{aligned}$$

Hence, we get that

$$\begin{aligned} (1 - \varepsilon) \text{cost}(P, I, \{q\}) &\leq \text{cost}(C, I, \{q\}) \\ &\leq (1 + \varepsilon) \text{cost}(P, I, \{q\}) \end{aligned}$$

by setting  $\varepsilon = (\varepsilon/48)^2$ . □

**Theorem 7.** *For every real  $\varepsilon > 0$  and for every positive integer  $\Delta$ , if a set of  $n$  points  $P$  is a subset of  $\Delta^d$ , that is, the points lie on a grid, and if  $C_0$  is the output of STEP-0( $P, \varepsilon$ ) then  $|C_0| = O(\frac{\log(\Delta dn)}{\varepsilon})$ .*

## 5 $2^h$ -Approximation Of Optimal Decision Trees

Let  $A, B \in \mathbb{R}$  be a pair of reals and let  $\alpha : [A, B] \times [A, B] \rightarrow \mathbb{R}_{\geq 0}$  be a continuous nonnegative function such that if  $t_1 \leq t_2 \leq t_3 \leq t_4$  then  $\alpha(t_2, t_3) \leq \alpha(t_1, t_4)$  for every  $t_1, t_2, t_3, t_4 \in [A, B]$  and  $\alpha(t, t) = 0$  for every  $t \in [A, B]$ .

Let  $\beta : [A, B] \times [A, B] \times \mathbb{Z}_{\geq 0} \rightarrow \mathbb{R}$  be defined as follows:

$$\beta(a, b, h) := \begin{cases} \alpha(a, b) & h = 0 \\ \min_{x \in [a, b]} \beta(a, x, h-1) + \beta(x, b, h-1) & h > 0 \end{cases}$$

Let  $\gamma, \delta : [A, B] \times [A, B] \times \mathbb{Z}_{\geq 0} \rightarrow \mathbb{R}$  be a pair of mutually recursive functions defined as follows:

$$\gamma(a, b, h) := \begin{cases} \alpha(a, b) & h = 0 \\ 2\gamma(a, \delta(a, b, h), h-1) & h > 0 \end{cases}$$

and

$$\delta(a, b, h) := \min \{x \in [a, b] \mid \gamma(a, x, h-1) = \gamma(x, b, h-1)\}.$$

**Lemma 1.** *Let  $h \in \mathbb{Z}_{>0}$  be a positive integer. Let  $a, b \in [A, B]$  be a pair of real numbers such that  $a \leq b$ . Then*

$$\gamma(a, b, h) \leq 2^h \beta(a, b, h)$$

*Proof.* We prove by induction on  $h$ .

Basis:  $h = 0$ . Since  $\gamma(a, b, 0) = \beta(a, b, 0) = \alpha(a, b)$  the claim follows immediately.

We now assume that the claim is true for  $h-1$  and prove it for  $h$ . Let  $x^* \in [a, b]$  be a real number such that

$$\beta(a, x^*, h-1) + \beta(x^*, b, h-1) = \beta(a, b, h)$$

and let  $x' \in [a, b]$  be a real number such that

$$\gamma(a, x', h-1) = \gamma(x', b, h-1).$$

We assume that for every  $a', b' \in [A, B]$ ,  $a' \leq b'$ ,

$$\gamma(a', b', h-1) \leq 2^{h-1} \beta(a', b', h-1)$$

and we aim to prove that

$$\gamma(a, b, h) \leq 2^h \beta(a, b, h).$$

We skip the proof that if  $t_1 \leq t_2 \leq t_3 \leq t_4$  then  $\beta(t_2, t_3, h-1) \leq \beta(t_1, t_4, h-1)$  for every  $t_1, t_2, t_3, t_4 \in [A, B]$  and that  $\beta(t_1, t_2, h-1) \leq \gamma(t_1, t_2, h-1)$  for every  $t_1, t_2 \in \mathbb{R}$  (due to optimality of  $\beta$ ).

Let's assume w.l.o.g that  $x^* \geq x'$  (the proof is symmetrical for the second case). Then  $\beta(a, x^*, h-1) \geq \beta(a, x', h-1)$  and therefore

$$\begin{aligned} 2^{h-1} \beta(a, b, h) &= 2^{h-1} \beta(a, x^*, h-1) + 2^{h-1} \beta(x^*, b, h-1) \\ &\geq 2^{h-1} \beta(a, x', h-1) \geq 2^{h-1} \gamma(a, x', h-1) \end{aligned}$$

and since we assumed (by induction) that

$$\gamma(a, x', h-1) \leq 2^{h-1} \beta(a, x', h-1)$$

we got that

$$2^{h-1} \beta(a, b, h) \geq 2^{h-1} \beta(a, x', h-1) \geq \gamma(a, x', h-1)$$

and therefore

$$\gamma(a, b, h) = 2\gamma(a, x', h-1) \leq 2^h \beta(a, b, h).$$

□
